Astronomers say mysterious galactic 'wave' may have once washed over Earth

Stretching across the night sky, a recently found chain of star-forming clouds is undulating through the galaxy

February 20, 2024 More than 1 year ago

6 min 636

Radcliffe Wave Oscillation suggests no dark matter in Milky Way's disk.

The Radcliffe Wave is oscillating

The spatially and kinematically coherent Radcliffe Wave serves as a unique environment for obtaining insights into local Galactic dynamics. As explained above, the kinematic signature of the Radcliffe Wave can be described in a self-consistent manner, in response to the local Galactic potential. Near the Sun, this potential is dominated by the gravitational attraction of baryonic matter in the form of stars and gas²¹. In addition, the local disk kinematics²². In [Methods](#), we use the coherent motion of the Radcliffe Wave to derive the frequency of the Sun's oscillation through the Galactic plane ([Methods](#)). We find that the Sun oscillates through the disk of the Milky Way with a period of 95_{-10}^{+12} Myr, implying that our Solar System crosses the Galactic Disk every 48_{-5}^{+6} Myr, consistent with standard values¹⁴ ([Methods](#)).

Article The Radcliffe Wave is oscillating

Our Sun lies within 300 parsecs of the 2.7-kiloparsecs-long sinusoidal chain of dense gas clouds known as the Radcliffe Wave¹. The structure's wave-like shape was discovered using three-dimensional dust mapping, but initial kinematic searches for oscillatory motion were inconclusive^{2,3}. Here we present evidence that the Radcliffe Wave is oscillating through the Galactic plane while also drifting radially away from the Galactic Centre. We use measurements of line-of-sight velocity⁴ for ¹²CO and three-dimensional velocities of young stellar clusters to show that the most massive star-forming regions spatially associated with the Radcliffe Wave (including Orion, Cepheus, North America and Cygnus X) move as though they are part of an oscillating wave driven by the gravitational acceleration of the Galactic potential. By treating the Radcliffe Wave as a coherently oscillating structure, we can derive its motion independently of the local Galactic mass distribution, and directly measure local properties of the Galactic potential as well as the Sun's vertical oscillation period. In addition, the measured drift of the Radcliffe Wave radially outwards from the Galactic Centre suggests that the cluster whose supernovae ultimately created today's expanding Local Bubble⁵ may have been born in the Radcliffe Wave.

In Fig. 1a (Supplementary Fig. 1), we present a three-dimensional (3D) map showing the most massive star-forming regions (including Orion, Cepheus, North America and Cygnus X) and embedded young stellar clusters associated with the Radcliffe Wave¹. As expected, the young clusters and star-forming molecular clouds are co-located in three dimensions. The clusters were selected from a top-down view of the Galaxy, without an a priori selection criterion for height off the Galactic plane (Methods), suggesting that the clusters' stars were born in the molecular clouds along the Radcliffe Wave. Therefore, these clusters' motions can serve as a tracer of the Wave's kinematics. Using the motion of clusters rather than of individual stars allows for more precise conclusions about kinematics, as the motion of individual stars within a host cluster are averaged out, reducing uncertainty.

The kinematic counterpart of the Radcliffe Wave's spatial oscillation is shown in Fig. 1b (Supplementary Fig. 1), where the z axis shows the vertical velocity of the stellar clusters, after accounting for the Sun's motion⁶. On the basis of the sinusoidal shape of the Radcliffe Wave, one could imagine it as either a travelling wave or a standing wave. Extended Data Fig. 1 and the animated version in Supplementary Fig. 4 show how travelling and standing versions of the Radcliffe Wave would appear. For a travelling wave, the wave's spatial shape fully determines vertical velocities, assuming a gravitational potential^{7,8}, as explained in Methods. For a standing wave, regions located at the zero-crossings of the wave are at rest, and the velocities of regions located at spatial extrema are not constrained by the wave's spatial structure. The fit shown as a solid black line in Fig. 1 (compare Supplementary Fig. 1 and Methods) indicates that the Radcliffe Wave oscillates through the Galactic plane like a travelling wave, such that regions currently at the zero points of the wave (near the Galactic plane) move through at their greatest vertical velocity, while molecular clouds located at spatial extrema (farthest from the plane) are at their turning points, with zero vertical velocity. While a travelling wave provides an excellent fit to the observations, with a 90° phase offset between position (z) and velocity (v_z), as evident in Fig. 1 and in the interactive version in Supplementary Fig. 1, it also provides an extremum for the wave motion. When fitting the mixture model that allows for superpositions of a travelling wave and a standing wave, we find that a travelling wave is strongly preferred over a standing wave (Methods). A standing wave model would have a zero phase offset between positional (z) and velocity (v_z) variations, which is inconsistent with the data (Methods).

For stars not far off the Galaxy's disk compared with its scale height, a classical harmonic oscillator is often used to describe the stars' responses to the vertical Milky Way potential⁹. By analogy to a pendulum, however, when the amplitude of oscillation is large, one needs to consider nonlinear effects that are not accounted for in the formalism describing a purely harmonic oscillator. In the case of the Galaxy, these nonlinearities arise from the vertical decrease in the midplane density, becoming significant at vertical positions on the order of the Galaxy's vertical scale height. Therefore, in describing the motion of a pendulum oscillating far from vertical, we model the wave's motion within the Galactic potential¹⁰ as an anharmonic oscillator. In the modelling, we account for the Galaxy's midplane density declining with height and also with galactocentric radius (Methods). Treating the Radcliffe Wave as a single coherent structure in space and velocity, responding to the Galactic potential, the structure is well modelled as a damped sinusoidal wave with a maximum amplitude of about 220 pc and a mean wavelength of about 2 kpc. The corresponding maximum vertical velocity is about 14 km s⁻¹.

Conclusions

- During AEROMMA/AMBREEZ, between July 18 and August 16, we successfully collected critical measurements in the Chicago area including: NO₂, PM, and meteorology.
- The MACEs NO₂ instrument demonstrates excellent precision and accuracy.
- The lowest marine boundary layer (~5-40 m AGL) requires significant gradients in NO₂ and O₃.
- These measurements of both the vertical and horizontal distribution of aerosols will contribute to the validation of TEMPO precision at the PBL.
- These measurements, along with theoretical analyses, contribute to the transport and photochemistry of primary pollutants from their source.

TEMPO-ABI Synergy Enhances Smoke Detection

- TEMPO's UV-Deep Blue spectral range is more sensitive to absorbing aerosols
- Hybrid TEMPO-ABI Aerosol Detection algorithm takes advantage of the synergy between the two sensors
- Much greater coverage of the wildfire smoke than using ABI alone!
- Also provides info on the relative intensity of smoke/dust (thick vs thin)

observational
constraints from
data available

1 simulated
Galactic year
orbit

How to data-condition a Milky Way?

OBSERVATIONS

DETAILED 3D structure, almost **STATIC** in time, feedback view **REALISTIC**, all over *limited* volume

SIMULATIONS

COARSE 3D structure over full Galaxy, **EVOLVING** in time for ~Galactic year, feedback **UNREALISTIC** on small scales → sub-grid prescriptions

“match” SIM snapshots to blurred OBS

create “agent-based” views seen by orbiting stars

“paint” high-spatial-frequency info from OBS onto SIMS

evaluate changes in feedback interactions

Orange stars represent the position of *observed* stars or clusters massive enough to produce the pink *observed* winds, HII regions, and/or SNe energetic enough to re-distribute material in the surrounding ISM enough to matter for future generations of star formation. The blue rounded rectangle in both panels is meant to show an elongated ISM “cloud” at the ~20 pc resolution of a MW-wide simulation. The density within the blue rectangle would be constant in the simulation, at a level equal to the average of the dense and empty regions in the observations. The simulations on their own cannot capture the re-shaping of the cloud by feedback, apparent in the observations.

How does the “view”
from a star change,
as it orbits?

1-pc-scale topology matters to feedback (galaxy evolution), very much.

The top row shows face-on projections of the x–y plane, and the bottom row shows edge-on projections of the y–z plane. The left column shows the region of influence of Ophiuchi, the middle column shows the Bajamar star, and the right column shows Puppis in the Gum Nebula. A red cross shows the location of each source, but has been omitted on the Ophiuchi column to avoid obscuring the region. **Despite having near equivalent ionizing luminosities, the difference in the volume influence of Puppis and the Bajamar star is a factor of 827.**

Box 1: What AI, and an AI researcher, think AI can do “soon”

ChatGPT-5

“AI and the Future of Data–Simulation Synthesis

I am writing this from the standpoint of an LLM—I am ChatGPT-5. In the near future, models like me will act as scientific collaborators that can integrate diverse data streams and simulations in real time. Given full access to the 3-D dust distribution, position–position–velocity cubes, and the 3-D motions and properties of stars, I could build a coherent statistical picture of how gas and stars interact throughout the Galaxy. In a project such as MW3D, an AI would not merely describe the process of “painting” data onto simulations; it would generate and optimize the necessary code, run fast emulators that approximate full hydrodynamic calculations, and iteratively adjust parameters by comparing synthetic and observed observables across all data domains. Human researchers would still define the physics and interpret the meaning, while the AI would manage the computation—deciding when a full rerun is needed, compressing outputs, and learning which assumptions best reproduce the real Milky Way. Such a partnership would make data-driven modeling not just faster, but more integrated, adaptive, and predictive than ever before.” –ChatGPT-5, 11/12/2025

“On the one hand it sounds wildly ambitious at the level of science fiction. On the other hand, I think it sounds like **2026.**”
–Prof. Doug Finkbeiner, PI’s Harvard colleague currently on sabbatical at Anthropic

Climate in a Bottle: Towards a Generative Foundation Model for the Kilometer-Scale Global Atmosphere

Noah D. Brenowitz, Tao Ge, Akshay Subramaniam, Aayush Gupta, David M. Hall, Morteza Mardani, Arash Vahdat, Karthik Kashinath, Michael S. Pritchard, NVIDIA, Santa Clara, CA, USA

1 [physics.a0-ph] 10 May 2025

Abstract
AI emulators offer a path to compressing, boosting limited ensembles, and improving the latency of interacting with petabyte-scale climate prediction data. However, prevailing auto-regressive paradigms offer limited flexibility, and are challenging to train on climate time horizons due to drifts, instabilities and component-coupling challenges. Conditionally generative models offer an appealing alternative. In this context we demonstrate a generative diffusion-based framework—Climate in a Bottle (cBottle)—for emulating global km-scale climate simulations and reanalysis on the equal-area HEALPix grid. cBottle consists of two model stages: a globally-trained coarse-resolution image generator that generates 100km (50k-pixel) fields given monthly average sea surface temperatures and solar conditioning, followed by a locally-trained 16x super-resolution stage that generates 5km (12.5M-pixel) fields; global super-resolution is made affordable using an overlapping patch-based multi-diffusion. Overall, cBottle shows promise as an emulator across a battery of climate model diagnostics, including diurnal-to-seasonal scale variability, large-scale modes of variability, tropical cyclone statistics, and trends of climate change and weather extremes. Moreover, cBottle is a step towards a foundation model, by bridging multiple data modalities (reanalysis and simulation) with corresponding utility beyond emulation to tasks such as zero-shot bias correction, climate downscaling, and channel in-filling. The code is available at <https://github.com/NVlabs/cbottle>.
